Project Structure

The Project layout for the Customer project has been adjusted since task 1, where the project layout adheres to the Domain Model pattern. Following the Domain-Driven Design building blocks for Domain Model Pattern; the customer, product and order projects have been adjusted to conform to this pattern.

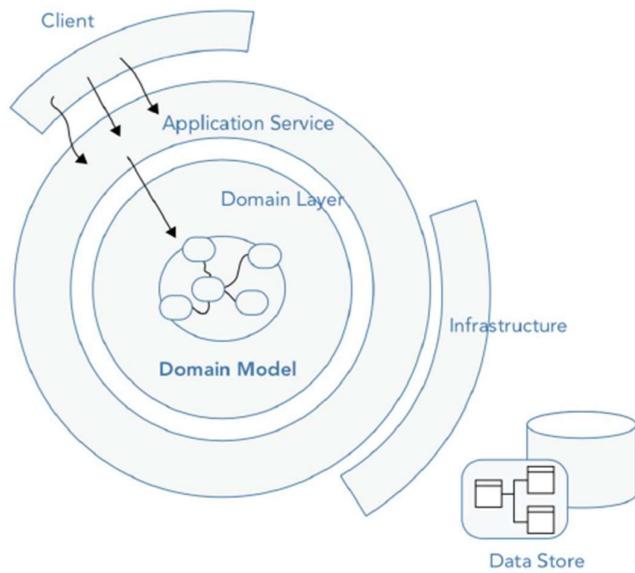

Figure 1.1. Domain Model pattern

UML diagrams are constructed to represent the Customer, Product and Order classes to represent the project to the Domain Model pattern accurately as possible.

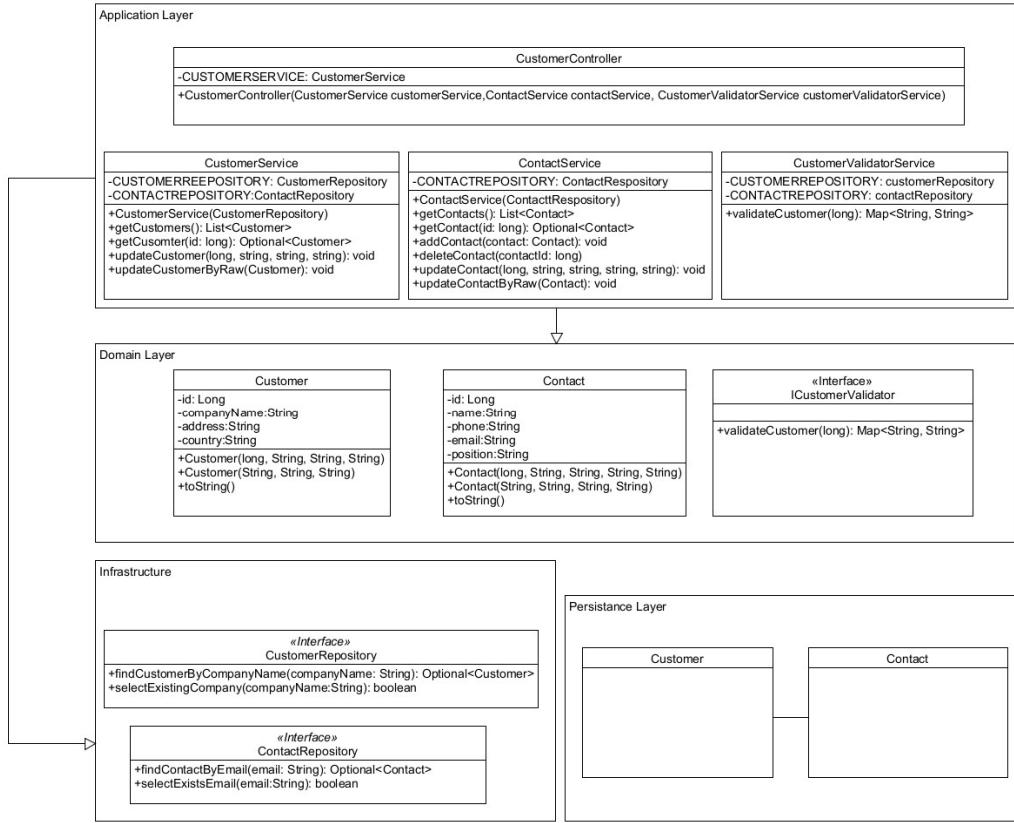

Figure 1.2 Customer Domain Model

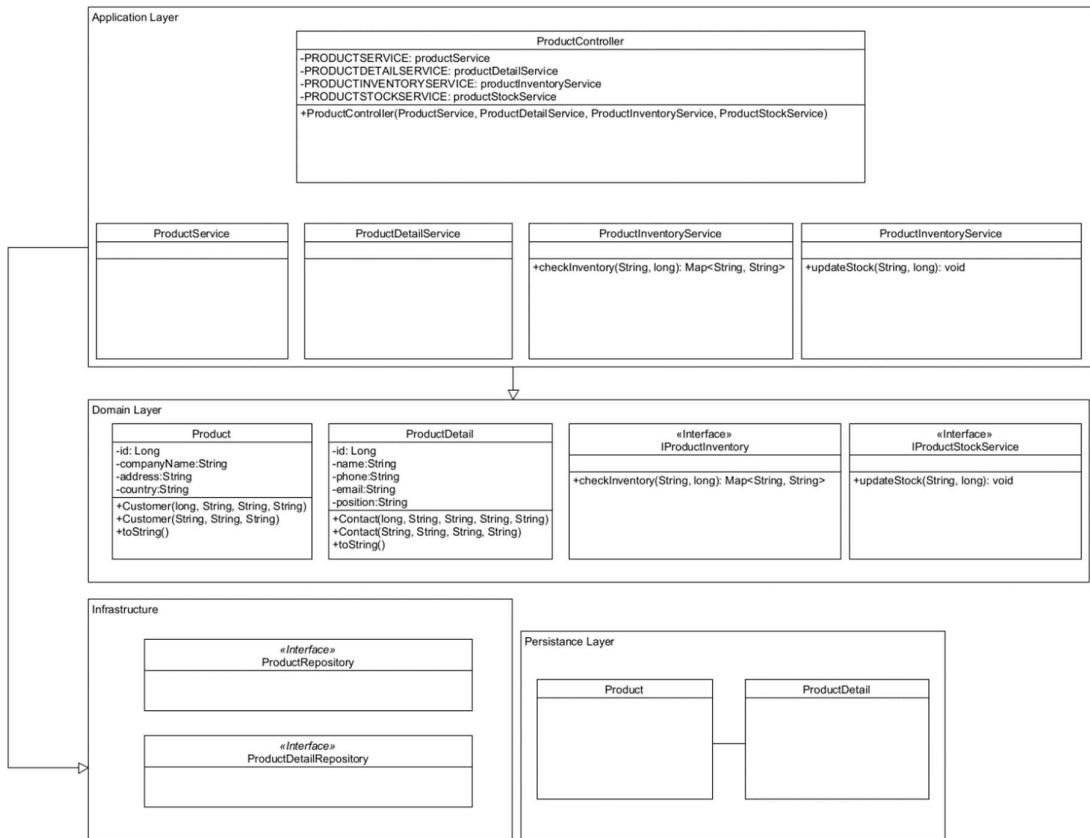

Figure 1.3 Product Domain Model

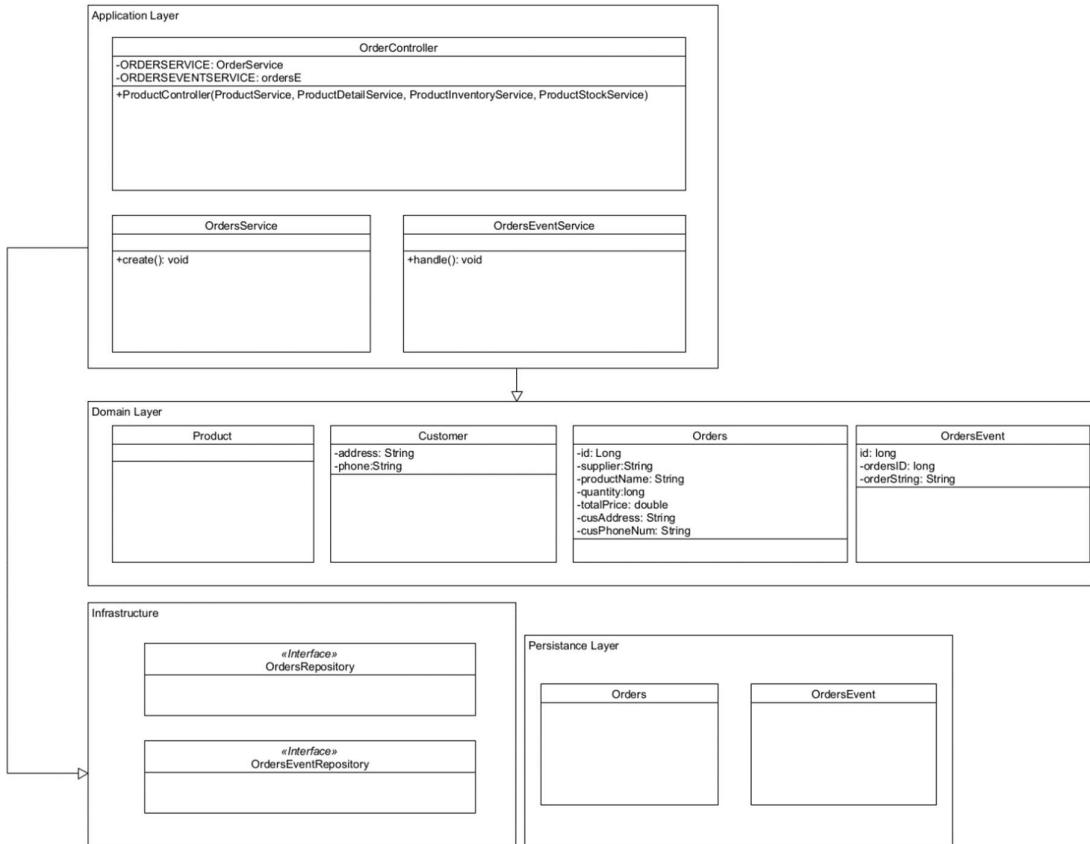

Figure 1.4 Order Domain Model

These UML diagrams replicate the Domain models as closely as possible in terms of the project structure. These models represent also models the N-tier architecture of each application. The representations do not include all functionalities but rather present how each tier is accessed and layered when the user interacts with the system. The project structures in the figure below replicate the N-tier architecture by layering the layers in packages. Except for the exception package, where this package acts as a layer that is not part of the N-tier architecture but rather a package for extending existing Exceptions for customized error messages.

When representing the N-tier architecture, the application layer contains the controller package or layer, which in turn acts as the API Layer. Where the Service Layer of the N-Tier architecture is represented by the Domain Layer. As for the data-access layer, this is contained in the infrastructure package with the persistence layer reflects off the domain models in a Table Module like pattern.

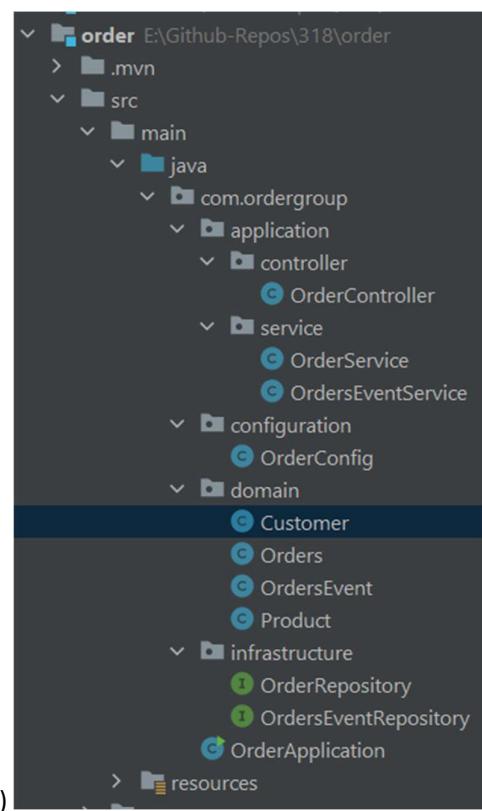

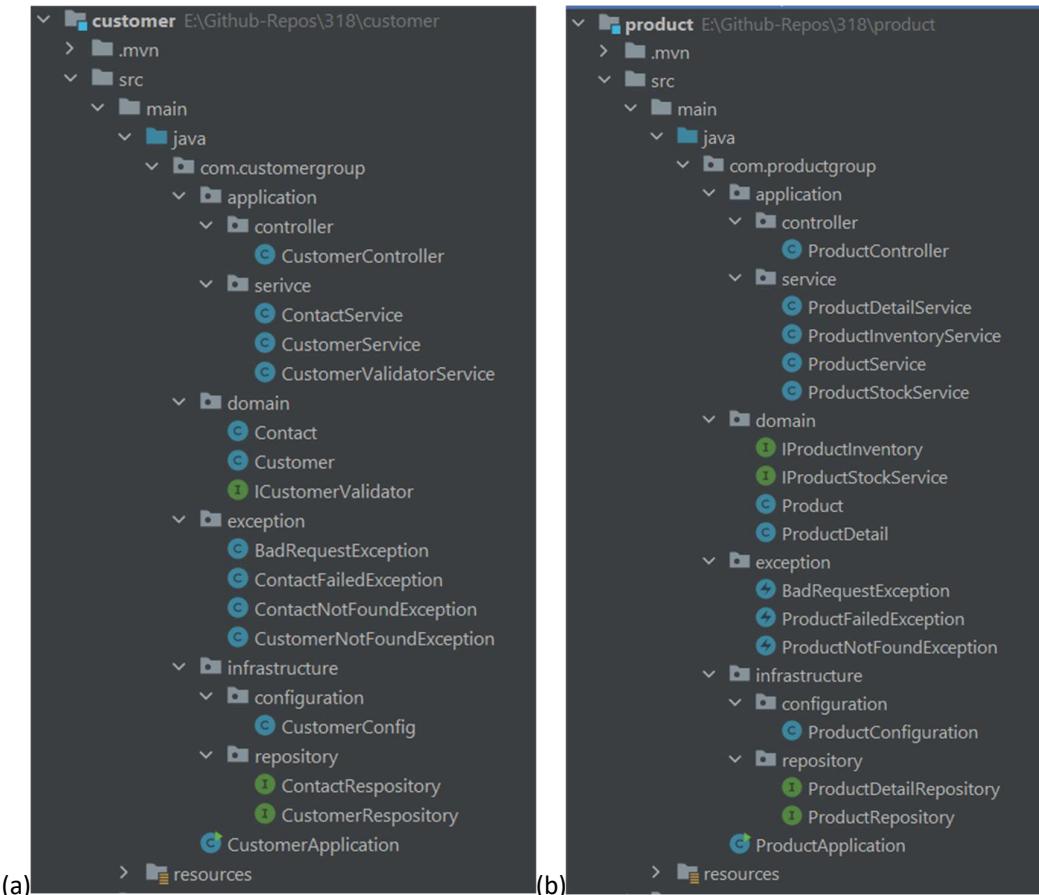

Figure 2. Project Layout of (a) Customer, (b) Product and (c) Order applications.

As seen in figure 2, the packages have been aligned with the multi-tier architecture where the API layer containing the HTTP endpoints lies within the Application package. The ‘Application’ package contains both Application services and implemented Domain services for Customer, Product and Order as seen in figure 2(a), (b) and (c). This package also serves to orchestrate the REST services only (endpoints) and contain no business logic while domain services such as ‘CustomerValidatorService’, ‘ProductInventoryService’ and ‘ProductStockStockService’ contain business rules. The same applies to OrdersService. The domain services are implemented within the application package, by the implementation of the interfaces defined in the domain layer. Controllers for each application *rest* within the application package to maintain consistency of the Domain model, which is where the application layer maintains as an access endpoint for the user/client.

The domain layer/package contains the models of the domain and is separated from the infrastructure and the presentation/Application package. This is accessed by the application layer and by extension, is responsible for managing and persisting states for the infrastructure. Also, within the subdomain of the Customer domain, a one-to-one mapping exists between the Customer and Contact entities. The same applies for the Product domain, between the subdomains where a one-to-one mapping exists between the Product and ProductDetails classes.

The infrastructure package concerns itself with the Persistence layer, which maps the object models to the database models. With the Customer application, the Customer object is represented as a table in the repository/database and the Contact object is represented as a separated table within the same repository. This trend is the same for the Product application, where are Product and ProductDetail objects are represented as the Product and ProductDetail tables within another repository, separate from the Customer Application. As well as for the Order Application, where the Orders and OrdersEvent objects are represented as tables in a separate repository. This also enforces physical boundaries to retain the integrity and autonomous property of bounded contexts, known as shared-nothing architecture thus implements the strategic pattern of physical boundaries.

As seen in both the Customer and Product applications, there exists an exception package for the primary focus on extending exception classes to throw custom error messages. Also, these applications contain a configuration folder within the infrastructure package for “hard-coding” some data entries for development and testing purposes.

Functionality of each Java Class

Customer

Application	
CustomerController	API Layer <ul style="list-style-type: none"> - Handles HTTP Request Mapping
ContactService	Application Service <ul style="list-style-type: none"> - Handles request mapping specifically to Contact
CustomerService	Application Service <ul style="list-style-type: none"> - Handles request mapping specifically to Customer - Handles mapping requests to updating Customer and
CustomerValidatorService	Domain Service (Implementation) <ul style="list-style-type: none"> - Handles business logic - Demonstrates behaviour for validating the customer. Parse customerID for validation, if there are no contact details attached to the customer, throw an error.
Domain	
Contact	<p>Entity</p> <ul style="list-style-type: none"> - Identifies contact by: <ul style="list-style-type: none"> o Name o Phone o Email o Position o Assigned (Value object) <p>Value Object</p> <ul style="list-style-type: none"> - assigned: <ul style="list-style-type: none"> o Describes the properties of contact and the characteristics of the Contact entity being assigned to the Customer entity. o The sub-optimal design has been implemented where assigned has been set as long. o Described as a numerical value. o Behaviour-rich in the sense that it sets a flag when the Contact object has been assigned to Customer and checks if has not already been assigned to another customer.
Customer	<p>Entity</p> <ul style="list-style-type: none"> - Identifies Customers by: <ul style="list-style-type: none"> o companyName o address o country
ICustomerValidator	Domain Service <ul style="list-style-type: none"> - Contains an Interface for Domain Service (implemented by CustomerValidator in application>service layer)
Infrastructure	
ContactRepository	A repository for Contact with custom Queries
CustomerRepository	A repository for Customer with custom Queries
CustomerConfig	A configuration containing pre-set variables (to save time entering values since we're lazy developers).

Product

Application	
ProductController	<p>API Layer</p> <ul style="list-style-type: none"> - Handles HTTP Request Mapping
ProductService	<p>Application Service</p> <ul style="list-style-type: none"> - Handles request mapping specifically to Product entity and corresponding repository.
ProductDetailService	<p>Application Service</p> <ul style="list-style-type: none"> - Handles request mapping specifically to ProductDetail and corresponding repository.
ProductInventoryService	<p>Domain Service (Implementation)</p> <ul style="list-style-type: none"> - Handles business logic - checkInventory() functionality checks if there's enough quantity of the product. If there aren't enough products, then this will throw an error.
ProductStockService	<p>Domain Service (Implementation)</p> <ul style="list-style-type: none"> - Handles business logic - updateStock() functionality updates the quantity of the product (only if the Order is successful). -
Domain	
IProductInventory	<p>Domain Service (Interface)</p> <ul style="list-style-type: none"> - An interface for the Domain Service for ProductInventoryService. -
IProductStockService	<p>Domain Service (Interface)</p> <ul style="list-style-type: none"> - An interface for the Domain Service for ProductStockService.
Product	<p>Entity</p> <ul style="list-style-type: none"> - Identifies Product by: <ul style="list-style-type: none"> o productCategory o name o price o stockQuantity o supplier <p>Value Object</p> <ul style="list-style-type: none"> - price <ul style="list-style-type: none"> o Invariant check where if a price entered is low than 0.0, this will throw an error. o Sub-optimal design has been implemented where representing the price as double has been chosen. <pre>if(price < 0.0) { throw new ProductFailedException("You cannot enter a product with a negative price."); } this.price = price;</pre>

	<ul style="list-style-type: none"> - stockQuantity <ul style="list-style-type: none"> o Invariant check where if a stockQuantity entered is lower than 0, this will throw an error. o Has been implemented as a long attribute rather than a class. <pre><code>if(stockQuantity < 0) { throw new ProductFailedException("You cannot enter a product with negative quantity"); } this.stockQuantity = stockQuantity;</code></pre> <p>Contains a one-to-one mapping with Product Detail ID</p>
ProductDetail	<p>Entity</p> <ul style="list-style-type: none"> - Identifies ProductDetail by: <ul style="list-style-type: none"> o Description o Comment <p>Contains a one-to-one mapping with product based on ID</p>
IProductInventory	<p>Domain Service</p> <ul style="list-style-type: none"> - Contains an Interface for Domain Service (implemented by ProductInventoryService in application>service layer)
IProductStockService	<p>Domain Service</p> <ul style="list-style-type: none"> - Contains an Interface for Domain Service (implemented by ProductStockService in application>service layer)
Infrastructure	
ProductDetailRepository	A repository for ProductDetail with custom Queries
ProductRespository	A repository for Product with custom Queries
ProductConfiguration	A configuration containing pre-set variables (to save time entering values since we're lazy developers).

Order

Application	
OrderController	<p>API Layer</p> <ul style="list-style-type: none"> - Handles HTTP Request Mapping
OrderService	<p>Application Service</p> <ul style="list-style-type: none"> - Handles request mapping specifically to Orders Entity as well corresponding repository - Further explanations of how OrderService meets aggregates will be explained in the next section.
OrdersEventService	<p>Application Service</p> <ul style="list-style-type: none"> - Implements event listener to handle OrdersEvent events and corresponding repository.
Domain	
Orders	<p>Entity</p> <ul style="list-style-type: none"> - Identifies Orders by: <ul style="list-style-type: none"> o supplier o productName

	<ul style="list-style-type: none"> ○ quantity ○ totalPrice ○ CusAddress ○ cusPhoneNum
OrdersEvent	<p>Entity</p> <ul style="list-style-type: none"> - Identifies OrdersEvent by: <ul style="list-style-type: none"> ○ OrderID ○ orderString
Customer	<p>Entity</p> <ul style="list-style-type: none"> - Identifies Customer by: <ul style="list-style-type: none"> ○ address ○ phone
Product	<p>Entity</p> <ul style="list-style-type: none"> - Identifies Product by: <ul style="list-style-type: none"> ○ productName ○ price ○ supplier
Infrastructure	
OrderRepository	A repository for Orders
OrdersEventRepository	A repository for OrdersEvent

Tactical Pattern – Domain Service

Domain Services have been implemented in the Customer application where ICustomerValidator represents the interface for the domain service. This interface contains the function validateCustomer, which enforces the business logic that “*a customer is only valid if they have contact details*”. The implementation of this logic exists in the service layer where the CustomerValidatorService implements this class.

As for the Production application, interface IProductStockService represents the business logic for updating stock once an order has been made and IProductInventory represents the business logic for checking the inventory if there’s enough quantity of the product. These interfaces exist in the domain package, where the implementations exist in the application service layer as seen in the ProductStockService and ProductInventoryService classes.

Specific to the Order application, domain events have also been implemented where the OrderService consist of the use of the ApplicationEventPublisher library as seen in the code below.

```
@Service
public class OrderService {

    private final OrderRepository orderRepository;
    private RestTemplate restTemplate;

    private ApplicationEventPublisher publisher;

    @Autowired
```

```

    public OrderService(OrderRepository
orderRepository, ApplicationEventPublisher publisher,
RestTemplateBuilder builder) {
        this.orderRepository = orderRepository;
        this.publisher = publisher;
        this.restTemplate = builder.build();
    }
}

```

This service publishes an event to the EventListener bean that calls for the handle() function that exists OrdersEventService class as seen in the code below.

```

@EventListener
public void handle(OrdersEvent ordersEvent) {
    try {
        ordersEventRepository.save(ordersEvent);

        //need to update stock
        System.out.println("Received order event, no
cap");
        String getOrderURL =
"http://localhost:8082/api/orders/" +
ordersEvent.getOrderID();
        System.out.println(getOrderURL);

        Orders order =
restTemplate.getForObject(getOrderURL, Orders.class);

        String updateStockUrl =
"http://localhost:8081/product/" +
order.getProductName() + "/quantity/" +
order.getQuantity();
        System.out.println(updateStockUrl);
        restTemplate.exchange(updateStockUrl,
HttpMethod.PUT, new HttpEntity<>(order, new
HttpHeaders()), Void.class);
    } catch (Exception e) {
        System.out.println("Message: " +
e.getMessage());
        throw new ResponseStatusException(
            HttpStatus.INTERNAL_SERVER_ERROR,
e.getMessage(), e
        );
    }
}

```

Tactical Pattern – Value Objects

Value Objects can be seen earlier within the Product class where price and stock quantity exist as integrated primitive data types in the class. This implement can be considered as a sub-optimal design choice due to the high coupling and cohesion between the value objects and the domain concept. However, reasonable assumptions that price and stock quantity cannot be negative justifies this sub-optimal design as it can be assumed (as of this current time in the project) that there is no more self-validation is needed.

Tactical Pattern - Aggregates

Within OrderService contains a create function that follows the Tactical pattern of Aggregates by preferring IDs over object references where an order is created by the use if the customer's ID as opposed to the customer object.

```
public void create(long custID, String productName,
long quanitity){

    try {
        // validate customer
        String validateURL =
"http://localhost:8080/api/customer/validate=" +
custID;
        Customer customer =
restTemplate.getForObject(validateURL, Customer.class);

        // check product inventory
        String checkInvURL =
"http://localhost:8081/product/checkInventory/productNa-
me=" + productName + "/quantity=" + quanitity;
        Product product =
restTemplate.getForObject(checkInvURL, Product.class);

        double totalPrice =
(Double.parseDouble(product.getPrice()) * quanitity);
        // order Event
        //create an order
        Orders order = new Orders(product.getSupplier()
            , productName
            , quanitity
            , totalPrice
            , customer.getAddress()
            , customer.getPhone()
        );

        orderRepository.save(order);
        //order Event
        OrdersEvent ordersEvent = new
```

```

OrdersEvent(order);
    publisher.publishEvent(ordersEvent);
}
catch (Exception e) {
    System.out.println("Message: " +
e.getMessage());
    throw new ResponseStatusException(
        HttpStatus.INTERNAL_SERVER_ERROR,
e.getMessage(), e
    );
}
}

```

Examples of Input and Output

Original GET request to customer

The screenshot shows a POSTMAN interface with the following details:

- Method:** GET
- URL:** http://localhost:8080/api/customer
- Params:** Query Params (Key: Value)
- Body:** Pretty (JSON output)
- Response Body:**

```

1 [
2   {
3     "id": 1,
4     "companyName": "Apple",
5     "address": "Somewhere in FreedomLand",
6     "country": "U.S.A"
7   },
8   {
9     "id": 2,
10    "companyName": "Tesla",
11    "address": "3500 Deer Creek Road Palo Alto, CA 94304",
12    "country": "U.S.A"
13  }
14 ]

```

Figure 3.1 – GET request for customer

USE CASE 1: Create/update customer

Create: POST request to customer

The screenshot shows the Postman interface with the following details:

- Method:** POST
- URL:** http://localhost:8080/api/customer
- Headers:** (9) - Headers tab is selected.
- Body:** (JSON) - Body tab is selected. The raw JSON content is:

```
1 {  
2   "companyName": "Banana",  
3   "address": "Somewhere in FreedomLand",  
4   "country": "FreedomLand"  
5 }
```

- Body Content:** The response body contains the number '1'.

Below the main interface, there is a note: "Note: The value of each key can be adjusted if needed, in JSON format."

At the bottom, there is a button labeled "GET customers after POST request".

The screenshot shows a Postman interface with a 'GET' request to 'http://localhost:8080/api/customer'. The 'Params' tab is selected, showing 'Query Params' with a table for KEY and VALUE. The 'Body' tab is selected, showing a JSON response with three objects (customer records) in a pretty-printed format. The JSON output is as follows:

```
5   "address": "Somewhere in FreedomLand",
6   "country": "U.S.A"
7   },
8   {
9     "id": 2,
10    "companyName": "Tesla",
11    "address": "3500 Deer Creek Road Palo Alto, CA 94304",
12    "country": "U.S.A"
13  },
14  {
15    "id": 3,
16    "companyName": "Banana",
17    "address": "Somewhere in FreedomLand",
18    "country": "FreedomLand"
19  ]
20 ]
```

Figure 4.2 – GET Request after successful ‘Create Customer’

In Figure 4.2 – it can be seen that the customer has been successfully inserted into the repository. A GET request to the endpoint ‘api/customer’ displays all the objects created in the Customer Repository with the new addition of the **Banana** company created in previously.

POST <http://localhost:8080/api/customer>

Params Authorization Headers (9) **Body** Pre-request Script Tests Settings

Body (JSON)

```

1 {
2   "companyName": "Banana",
3   "address": "39 Ferny Avenue, Wollongong",
4   "country": "North Korea"
5 }
```

Body Cookies Headers (4) Test Results

5     "error": "Bad Request",
6     "message": "Company Name: 'Tesla' is already taken!",
7     "path": "/api/customer/1"
8   }
9

```

Figure 4.6 – Updating customer with a company name “Tesla” which already exists in the database.

USE CASE 2: Create/update customer contact

Create Contact

Input:

The screenshot shows a Postman interface with a POST request to `http://localhost:8080/api/contact`. The 'Body' tab is selected, showing a JSON object with the following structure:

```
1
2   ...
3     "name": "Cake",
4     "phone": "+61-412-123-456",
5     "email": "cake@gmail.com",
6     "position": "positionTwo",
7     "dob": "1996-04-28"
```

Below the body, the 'Test Results' section shows a single entry with the value '1'.

Figure 5.1 – Updating customer with a company name “Tesla” which already exists in the database.

When sending a POST request to the contact API of creating a contact, a successful creation will result in no body. One value to keep in mind is the name attribute; where if there is a name that already exists in the database, this will throw an error as an assumption is made that each name is unique.

Curl:

```
curl --location --request POST 'http://localhost:8080/api/contact' \
--header 'Content-Type: application/json' \
--data-raw '{
  "name": "Cake",
  "phone": "+61-412-123-456",
  "email": "cake@gmail.com",
  "position": "positionTwo",
  "dob": "1996-04-28"
}'
```

Note: The value of each key can be adjusted if needed, in JSON format.

Output:

The screenshot shows a POST request to `http://localhost:8080/api/contact`. The response body is a JSON array containing three contact objects:

```

3   "id": 1,
4     "name": "Peter",
5     "phone": "+61-412-123-456",
6     "email": "peter@gmail.com",
7     "position": "positionOne",
8     "assigned": -1,
9     "customer": null
10    },
11  {
12    "id": 2,
13    "name": "Pineapple",
14    "phone": "+61-412-123-456",
15    "email": "pineapple@gmail.com",
16    "position": "positionTwo",
17    "assigned": -1,
18    "customer": null
19  },
20  {
21    "id": 3,
22    "name": "Cake",
23    "phone": "+61-412-123-456",
24    "email": "cake@gmail.com",
25    "position": "positionTwo",
26    "assigned": -1,
27    "customer": null
28  }
29

```

Figure 5.2– Output of creating a new contact

After successful POST, we can view the new entry with a GET request to the contact endpoint as seen in figure 3.9.

Curl:

```
curl --location --request GET 'http://localhost:8080/api/contact'
```

Update Contact

Input:

PUT request can be sent to `api/contact/{contactId}` using key parameters where the key value are attributes of Contact and values containing the value to update/assign the contact object.

Example:

<http://localhost:8080/api/contact/3?name=TheApple&phone=911&email=apple@apple.com&position=positionfour>

The screenshot shows a PUT request to `http://localhost:8080/api/contact/3` with the following parameters:

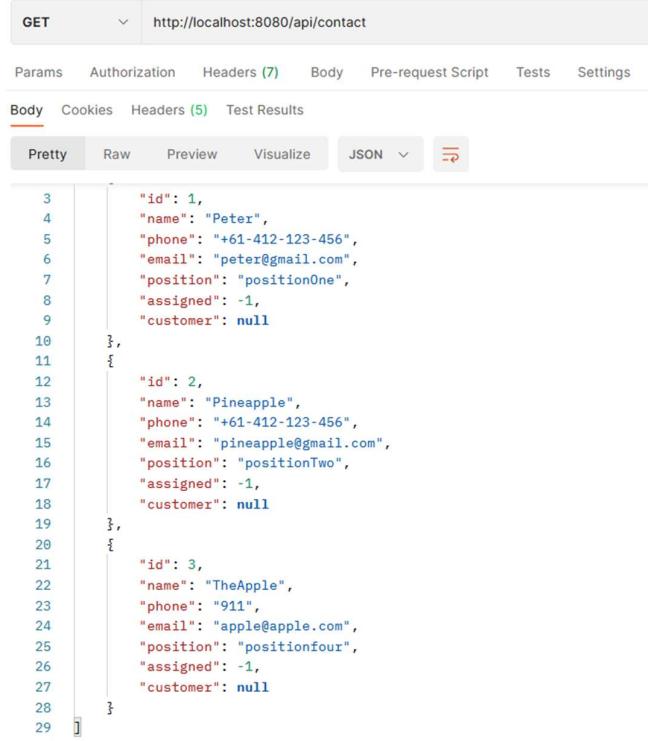

Key	Value	Description
name	TheApple	
phone	911	
email	apple@apple.com	
position	positionfour	

Figure 5.3 – Update request of updating a contact.

Curl equivalent:

```
curl --location --
request PUT 'http://localhost:8080/api/contact/3?name=TheApple&phone=911&email=apple@apple.com&position=positionfour'
```

Output:

The screenshot shows the Postman application interface. At the top, there is a header bar with 'GET' selected and the URL 'http://localhost:8080/api/contact'. Below the header are tabs for 'Params', 'Authorization', 'Headers (7)', 'Body', 'Pre-request Script', 'Tests', and 'Settings'. The 'Headers (5)' tab is currently active. Underneath these tabs, there are buttons for 'Pretty' (selected), 'Raw', 'Preview', 'Visualize', and 'JSON' (with a dropdown menu). The main content area displays a JSON array of three contact objects, each with properties: id, name, phone, email, position, assigned, and customer. The contacts are numbered 1, 2, and 3.

```

Figure 5.4 – Output of updating contact 3

Update Customer with contact details

Customers can be updated with adding contact details by sending a PUT request to
Api/customer/{customerId}/contact/{contactId}

Where {customerId} and {contactId} are both replaced by a number corresponding to the ID of the objects.

Input:

```
curl --location --request PUT 'http://localhost:8080/api/customer/2/contact/1'
```

This is where customer with the ID 2 is assigned with the contact of ID 1.

Output:

The screenshot shows a Postman request for a GET operation at `http://localhost:8080/api/contact`. The response body is displayed in JSON format, showing a single contact object with ID 1. The contact has a nested customer object with ID 2, which contains company information like Tesla and its address.

```

1 [
2 {
3   "id": 1,
4   "name": "Peter",
5   "phone": "+61-412-123-456",
6   "email": "peter@gmail.com",
7   "position": "positionOne",
8   "assigned": 2,
9   "customer": {
10     "id": 2,
11     "companyName": "Tesla",
12     "address": "3500 Deer Creek Road Palo Alto, CA 94304",
13     "country": "U.S.A"
14   }
15 }

```

Figure 5.5 – Output of updating contact 3

USE CASE 3: Look up customer basic info and contact

Look up customer basic info can be achieved via the contact API, this is due the JSON ignore defined in the Customer.java entity class.

To grab all customer basic info and contact, a GET request can be sent to 'api/contact'.

The screenshot shows a Postman request for a GET operation at `http://localhost:8080/api/contact`. The response body is displayed in JSON format, showing three customer objects with IDs 1, 2, and 3. Each customer object includes their basic details and a nested contact object.

```

1 [
2 {
3   "id": 1,
4   "name": "Peter",
5   "phone": "+61-412-123-456",
6   "email": "peter@gmail.com",
7   "position": "positionOne",
8   "assigned": 2,
9   "customer": {
10     "id": 2,
11     "companyName": "Tesla",
12     "address": "3500 Deer Creek Road Palo Alto, CA 94304",
13     "country": "U.S.A"
14   }
15 },
16 {
17   "id": 2,
18   "name": "Pineapple",
19   "phone": "+61-412-123-456",
20   "email": "pineapple@gmail.com",
21   "position": "positionTwo",
22   "assigned": -1,
23   "customer": null
24 },
25 {
26   "id": 3,
27   "name": "TheApple",

```

Figure 6.1 – Looking up all customer basic info and contact

or

```
curl --location --request GET 'http://localhost:8080/api/contact'
```

Looking up a specific customer basic info and contact

This can be achieved by sending a GET request to the contact endpoint with an ID corresponding to the contact ID. For example,

Input:

<http://localhost:8080/api/contact/1>

or

```
curl --location --request GET 'http://localhost:8080/api/contact/1'
```

Output:

The screenshot shows the Postman application interface. At the top, there is a header bar with 'GET' selected and the URL 'http://localhost:8080/api/contact/1'. Below the header, there are tabs for 'Params', 'Authorization', 'Headers (7)', 'Body', 'Pre-request Script', 'Tests', and 'Settings'. Under the 'Params' tab, there is a section titled 'Query Params' with a table. The table has two columns: 'KEY' and 'VALUE'. There is one row with 'Key' in the KEY column and 'Value' in the VALUE column. In the main content area, there are tabs for 'Body', 'Cookies', 'Headers (5)', and 'Test Results'. The 'Body' tab is selected and contains a 'Pretty' button, 'Raw' button, 'Preview' button, 'Visualize' button, and a 'JSON' dropdown set to 'Pretty'. Below these buttons is a JSON-formatted response. The response is as follows:

```
1
2
3
4
5
6
7
8
9
10
11
12
13
14
{
  "id": 1,
  "name": "Peter",
  "phone": "+61-412-123-456",
  "email": "peter@gmail.com",
  "position": "positionOne",
  "assigned": 2,
  "customer": {
    "id": 2,
    "companyName": "Tesla",
    "address": "3500 Deer Creek Road Palo Alto, CA 94304",
    "country": "U.S.A"
  }
}
```

Figure 6.2 – Looking a specific contact detail.

Looking up a contactID allows us to view the contact details and the customer it has been assigned. If there were to be no customer assigned to the contact details, this will print:

Figure 6.3 – Looking a specific contact containing no assignment to Customer.

USE CASE 4: Create/update product

Create: POST request to product

Product / <http://localhost:8081/product>

POST <http://localhost:8081/product>

Params Authorization Headers (8) Body **Pre-request Script Tests Settings**

none form-data x-www-form-urlencoded raw binary GraphQL **JSON**

```

1 {
2   "productCategory": "Beverage",
3   "productName": "Sprite",
4   "price": 2.35,
5   "stockQuantity": 15
6 }
7

```

Figure 7.1 – POST request for product

To create a product, a POST request is sent to /product endpoint with a body of raw text in JSON. An example of this in curl is provided below.

Curl example:

```
curl --location --request POST 'http://localhost:8081/product' \
--header 'Content-Type: application/json' \
```

```
--data/raw '{
    "productCategory": "Beverage",
    "productName": "Sprite",
    "price": 2.35,
    "stockQuantity": 15
}'
```

Note: The value of each key can be adjusted if needed, in JSON format.

GET products after POST request

The screenshot shows a Postman interface with a GET request to `http://localhost:8081/product`. The 'Body' tab is selected, displaying the JSON response:

```

6   "price": 1.05,
7   "stockQuantity": 10
8 },
9 {
10  "id": 2,
11  "productCategory": "Food",
12  "productName": "Hotdog",
13  "price": 10.0,
14  "stockQuantity": 5
15 },
16 {
17  "id": 3,
18  "productCategory": "Beverage",
19  "productName": "Sprite",
20  "price": 2.35,
21  "stockQuantity": 15
22 }
23 ]
```

Figure 7.2 – GET Request after successful ‘Create Product’

In Figure 3.3 – it can be seen that the product has been successfully inserted into the repository.

Product / <http://localhost:8081/product>

POST <http://localhost:8081/product>

Params Authorization Headers (8) **Body** Pre-request Script Tests Settings

none form-data x-www-form-urlencoded raw binary GraphQL **JSON**

```

1 {
2   "productCategory": "Beverage",
3   "productName": "Water",
4   "price": 2.35,
5   "stockQuantity": 15
6 }
7

```

Body Cookies Headers (4) Test Results Status: 500 Int

Pretty Raw Preview Visualize JSON

```

1 {
2   "timestamp": "2021-09-24T08:41:02.815+00:00",
3   "status": 500,
4   "error": "Internal Server Error",
5   "message": "A product with this name already exists!",
6   "path": "/product"
7 }

```

UPDATE CUSTOMER

PUT <http://localhost:8080/api/customer/3?companyName=Banana>

Params **Authorization** Headers (7) Body Pre-request Script Tests Settings

Query Params

KEY	VALUE	DESCRIPTION
<input checked="" type="checkbox"/> companyName	Banana	
Key	Value	Description

Body Cookies Headers (4) Test Results Status: 200 OK Time: 3ms

Pretty Raw Preview Visualize Text

```

1

```

Figure 7.3 – POST Request containing same productName
In Figure 3.4 entering a new product with a productName that already exists returns an error because productName is unique.

Figure 7.4 – PUT Request to customer with ID = 3
In Figure 3.5, a PUT request can be sent to the customer where id is 3. Key parameters can be used to update the companyName as seen in figure 3.5 where the key companyName is set to the value “Banana”.

```
curl --location --
request PUT 'http://localhost:8080/api/customer/3?companyName=Banana'
```

The screenshot shows the Postman interface with a successful GET request to `http://localhost:8080/api/customer/`. The response body is a JSON array of three customer objects:

```

1 [
2   {
3     "id": 1,
4     "companyName": "Apple",
5     "address": "Somewhere in FreedomLand",
6     "country": "U.S.A"
7   },
8   {
9     "id": 2,
10    "companyName": "Tesla",
11    "address": "3500 Deer Creek Road Palo Alto, CA 94304",
12    "country": "U.S.A"
13  },
14  {
15    "id": 3,
16    "companyName": "Banana",
17    "address": "Somewhere in Lalaland",
18    "country": "Lalaland"
19  }
20 ]

```

Figure 7.5 – GET Request after successful update

PUT request failed because companyName “Tesla” already exists

The screenshot shows a failed PUT request to `http://localhost:8080/api/customer/1?companyName=Tesla`. The query parameters include `companyName` set to `Tesla`. The response body is a JSON object indicating a bad request:

```

1 {
2   "timestamp": "2021-09-23T13:13:08.231+00:00",
3   "status": 400,
4   "error": "Bad Request",
5   "message": "Company Name: 'Tesla' is already taken!",
6   "path": "/api/customer/1"
7 }

```

Figure 7.6– Updating customer with a company name “Tesla” which already exists in the database.

USE CASE 5: Create/update product detail

Create Product Detail

Input:

The screenshot shows the Postman interface with a POST request to `http://localhost:8081/productDetail`. The `Body` tab is selected, showing the following JSON input:

```
1  {
2     ...
3     "description": "It is also a fluid",
4     ...
5     "comment": "Used to treat diabetes"
6 }
```

Curl:

```
curl --location --request POST 'http://localhost:8081/productDetail' \
--header 'Content-Type: application/json' \
--data-raw '{
    "description": "It is also a fluid",
    "comment": "Used to treat diabetes"
}'
```

Output:

Product-Detail / get all product details

GET http://localhost:8081/productDetail

Params Authorization Headers (6) Body Pre-request Script Tests Settings

Body Cookies Headers (5) Test Results

Pretty Raw Preview Visualize JSON

```

1 [
2   {
3     "id": 1,
4     "description": "It is a fluid",
5     "comment": "Everyone needs it in their lives",
6     "product": null,
7     "assigned": -1
8   },
9   {
10    "id": 2,
11    "description": "Large 15 pepperoni",
12    "comment": "Not from dominos.",
13    "product": null,
14    "assigned": -1
15  },
16  {
17    "id": 3,
18    "description": "It is also a fluid",
19    "comment": "Used to treat diabetes",
20    "product": null,
21    "assigned": -1
22  }
]

```

Figure 8.2 – Output of creating a new product detail
After successful POST, we can view the new entry with a GET request to the productDetail endpoint as seen in figure 8.2.

Curl:

```
curl --location --request GET 'http://localhost:8081/productDetail'
```

Update Product Detail

Input:
PUT request can be sent to productDetail/{productDetailId} using key parameters where the key value are attributes of Product Detail and values containing the value to update/assign the productDetail object.

Product-Detail / New Request

PUT http://localhost:8081/productDetail/2

Params ● Authorization Headers (8) **Body** ● Pre-request Script Tests Settings

none form-data x-www-form-urlencoded raw binary GraphQL **JSON**

```

1 {
2   "id": 2,
3   "description": "Sausig in a bun",
4   "comment": "No dogs were harmed in the process"
5 }

```

Figure 8.3 – Update request of updating a productDetail with id = 2.

Output:

The screenshot shows the Postman 'New Request' interface. The method is set to 'PUT' and the URL is 'http://localhost:8081/productDetail/2'. The 'Body' tab is selected, showing a JSON payload with two fields: 'description' and 'comment'. The 'description' field contains 'Sausig in a bun' and the 'comment' field contains 'No dogs were harmed in the process'.

```
1 {  
2   "description": "Sausig in a bun",  
3   "comment": "No dogs were harmed in the process"  
4 }
```

Figure 8.4 – Output of updating productDetails 2

Curl:

```
curl --location --request PUT 'http://localhost:8081/productDetail/2' \  
--header 'Content-Type: application/json' \  
--data-raw '{  
  "description": "This is a test",  
  "comment": "This should update product 2's details."  
}'
```

Update product with product details

Products can be updated with adding product details by sending a PUT request to /product/{productId}/productDetails/{productDetailsId}

Where {productId} and {productDetailsId} are both replaced by a number corresponding to the ID of the objects.

Input:

```
curl --location --request PUT 'http://localhost:8081/product/2/productDetail/2'
```

This is where product with the ID 2 is assigned with the productDetail of ID 2.

Output:

Product-Detail / get all product details

GET http://localhost:8081/productDetail/

Params Authorization Headers (6) Body Pre-request Script Tests Settings

Body Cookies Headers (5) Test Results

Pretty Raw Preview Visualize JSON

```

5   "comment": "Everyone needs it in their lives",
6   "product": null,
7   "assigned": -1
8 },
9 {
10  "id": 2,
11  "description": "Sausig in a bun",
12  "comment": "No dogs were harmed in the process",

7       "id": 1,
8       "productCategory": "Beverage",
9       "productName": "Water",
10      "price": 1.05,
11      "stockQuantity": 10
12    },
13    "assigned": 1
14  },
15  [
16    {
17      "id": 2,
18      "description": "Large 15 pepperoni",
19      "comment": "Not from dominos.",
20      "product": null,
21      "assigned": -1
22  ],

```

Figure 9.1 – Looking up all products basic info and product detail
or

```
curl --location --request GET 'http://localhost:8081/productDetail'
```

Looking up a specific product basic info and product detail
This can be achieved by sending a GET request to the productDetail endpoint with an ID corresponding to the productDetail ID. For example,

Curl:

```
curl --location --request GET 'http://localhost:8081/productDetail/3'
```

Output:

GET http://localhost:8081/productDetail/3

Params Authorization Headers (6) Body Pre-request Script Tests Settings

Body Cookies Headers (5) Test Results

Pretty Raw Preview Visualize JSON

```

1  [
2   {
3     "id": 3,
4     "description": "It is also a fluid",
5     "comment": "Used to treat diabetes",
6     "product": {
7       "id": 3,
8       "productCategory": "Beverage",
9       "productName": "Sprite",
10      "price": 2.35,
11      "stockQuantity": 15
12    },
13    "assigned": 3
14  ],

```

Figure 9.2 – Looking a specific product detail

Looking up a productDetailID allows us to view the product details and the product it has been assigned. If there were to be no product assigned to the product details, this will print:

The screenshot shows the Postman interface with a GET request to `http://localhost:8081/productDetail/2`. The response is a 200 OK status with a body containing the following JSON:

```
1 "id": 2,
2 "description": "Large 15 pepperoni",
3 "comment": "Not from dominos.",
4 "product": null,
5 "assigned": -1
```

Figure 9.3 – Looking a specific productDetail with no assignment to a product

USE CASE 7: Create Order

Creating an order can be completed through the Orders API.

To create an order a POST request can be sent to `./orders` with the appropriate values in the request body

The screenshot shows the Postman interface with a POST request to `http://localhost:8082/api/orders`. The request body is set to `raw` and contains the following JSON:

```
1 {
2   "custID": "2",
3   "productName": "Hotdog",
4   "quantity": "5"
```

Figure 10.1– Creating a new order

Or

```

curl --location --request POST 'http://localhost:8082/api/orders' \
--header 'Content-Type: application/json' \
--data-raw '{
    "custID": "2",
    "productName": "Hotdog",
    "quantity": "5"
}'

```

This would return a '1' or true response if this was successful.

It would also appear when submitting a request for all orders as shown here

The screenshot shows the Postman interface. At the top, a GET request is defined with the URL <http://localhost:8082/api/orders>. The 'Params' tab is selected, showing a single parameter 'Key' with the value 'Key'. In the 'Body' section, the 'Pretty' tab is selected, displaying the JSON response:

```

1  [
2   {
3     "id": 1,
4     "suplier": "Random-street-vendor",
5     "productName": "Hotdog",
6     "quantity": 5,
7     "totalPrice": 50.0,
8     "cusAddress": "3500 Deer Creek Road Palo Alto, CA 94304",
9     "cusPhoneNum": "+61-412-123-456"
10    }
11 ]

```

Figure 10.2 – Successful order creation

Or

```
curl --location --request GET 'http://localhost:8082/api/orders'
```

Submitting a create order request first validates a customer by submitting a request to the customer application. Upon success, it will return a customer's address and phone number

The screenshot shows a POSTMAN interface with the following details:

- Method:** GET
- URL:** <http://localhost:8080/api/customer/validate=2>
- Params Tab:** Contains a single entry: "KEY" with value "Key".
- Body Tab:** Contains the following JSON response:

```
1 "address": "3500 Deer Creek Road Palo Alto, CA 94304",
2 "phone": "+61-412-123-456"
3
4
```
- Headers Tab:** Shows 5 headers.
- Test Results Tab:** Not visible in the screenshot.

Figure10.3 – Customer Validation

Or

```
curl --location --request GET 'http://localhost:8080/api/customer/validate=2'
```

It then checks that there is enough product in stock with a request to the product application as shown here. Upon success, a unit price and supplier is returned.

The screenshot shows the Postman interface with a GET request to `http://localhost:8081/product/checkInventory/productName=Hotdog/quantity=5`. The 'Params' tab is selected, showing a single query parameter 'Key'. The response body is displayed in 'Pretty' format, showing product details:

```

1  {
2      "id": 1,
3      "name": "Hotdog",
4      "price": "10.0",
5      "supplier": "Random-street-vendor"
6  }

```

Figure 10.4 – Check Inventory

Or

```
curl --location --request GET
'http://localhost:8081/product/checkInventory/productName=Hotdog/quantity=5'
```

If this check fails, an exception will be shown

```

1  {
2      "timestamp": "2021-09-24T10:18:46.616+00:00",
3      "status": 500,
4      "error": "Internal Server Error",
5      "message": "There is not enough stock for product: Hotdog. The amount of
6          available stock: 0. The quantity you have requested for: 5",
7      "path": "/product/checkInventory/productName=Hotdog/quantity=5"
8  }

```

Figure 10.5 – Failed Check Inventory

After creating an order, an OrdersEvent is then published and event listener makes a request again to the Product Application to update the inventory of the specified item. This request looks like this:

The screenshot shows the Postman application interface. At the top, there is a header bar with a dropdown menu set to 'PUT' and a URL field containing 'http://localhost:8081/product/Hotdog/quantity/3'. Below the header are several tabs: 'Params' (which is selected), 'Authorization', 'Headers (8)', 'Body', 'Pre-request Script', 'Tests', and 'S'. Under the 'Params' tab, there is a section titled 'Query Params' with a table. The table has two rows: one with a 'KEY' column and a 'Value' column containing 'Key', and another row with empty columns. At the bottom of the interface, there is a navigation bar with tabs: 'Body', 'Cookies', 'Headers (4)', and 'Test Results'. The 'Body' tab is selected. Below the tabs are buttons for 'Pretty', 'Raw', 'Preview', 'Visualize', 'Text' (with a dropdown arrow), and a copy icon. The main body area contains the number '1'.

Figure 10.6 – Update Stock

Or

```
curl --location --request PUT 'http://localhost:8081/product/Hotdog/quantity/3'
```

USE CASE 8: Look up Customer basic info by order

Assumptions have been made that a customer's basic info includes only a customer's address and a customer's phone number.

Looking up this information up by order can be completed with the orders API

A GET request is made with the orderId as shown. The order being used is the same order shown in Figure 11.1

The screenshot shows the Postman interface with a GET request to `http://localhost:8082/api/orders/1/customer`. The 'Params' tab is selected, showing a single query parameter named 'Key'. The 'Body' tab is also visible below.

Body **Cookies** **Headers (5)** **Test Results**

Pretty Raw Preview Visualize **JSON** ▾

```
1 "address": "3500 Deer Creek Road Palo Alto, CA 94304",
2 "phone": "+61-412-123-456"
3
4
```

Figure 11.1 – Look up customer info by order
Or
`curl --location --request GET 'http://localhost:8082/api/orders/1/customer'`
If no such orderID exists, the request will receive the following response:

The screenshot shows a POSTMAN interface with the following details:

- Method:** GET
- URL:** <http://localhost:8082/api/orders/4/customer>
- Headers:** (7)
- Body:** (Pretty, Raw, Preview, Visualize, JSON)
- Query Params:** KEY: Key
- Response Headers:** (4)
- Response Body:**

```
1 "timestamp": "2021-09-24T10:34:18.970+00:00",
2 "status": 500,
3 "error": "Internal Server Error",
4 "message": "No value present",
5 "path": "/api/orders/4/customer"
```

Figure 11.2– Failed Look up customer info by order

USE CASE 9: Look up Product basic info by order

Assumptions have been made a products basic information consists of a product name, supplier and unit price.

Looking up this information by order can be done by using the orders API

A GET request is submitted with the orderId as shown below. The order being used is the same order shown in Figure 7.2.

Figure 12.1 – look up product info by order

Or

```
curl --location --request GET 'http://localhost:8082/api/orders/1/product'
```

If no such orderId exists, the request will receive the following response:

The screenshot shows a POSTMAN interface with the following details:

- Method:** GET
- URL:** <http://localhost:8082/api/orders/4/product>
- Params Tab (Active):** Contains a section for "Query Params" with a "KEY" field and a "Value" field containing "Key".
- Body Tab (Active):** Contains tabs for "Pretty", "Raw", "Preview", "Visualize", and "JSON". The "Pretty" tab is selected, displaying the following JSON response:

```
1
2   "timestamp": "2021-09-24T10:44:50.455+00:00",
3   "status": 500,
4   "error": "Internal Server Error",
5   "message": "No value present",
6   "path": "/api/orders/4/product"
7
```
- Headers Tab:** Shows 7 headers.
- Test Results Tab:** Shows 4 test results.

Figure 12.2 – failed look up product info by order

Instructions on Building JAR files

**Note – The Compiled JAR files for all projects will also be included with the source code in the Target Directories for each project*

With the use of IntelliJ's in-built Maven package and functionality, the **target** class was built using the 'install' functionality (We did not try to attempt to build the target class via command line). The target class will also be included in the ZIP file.

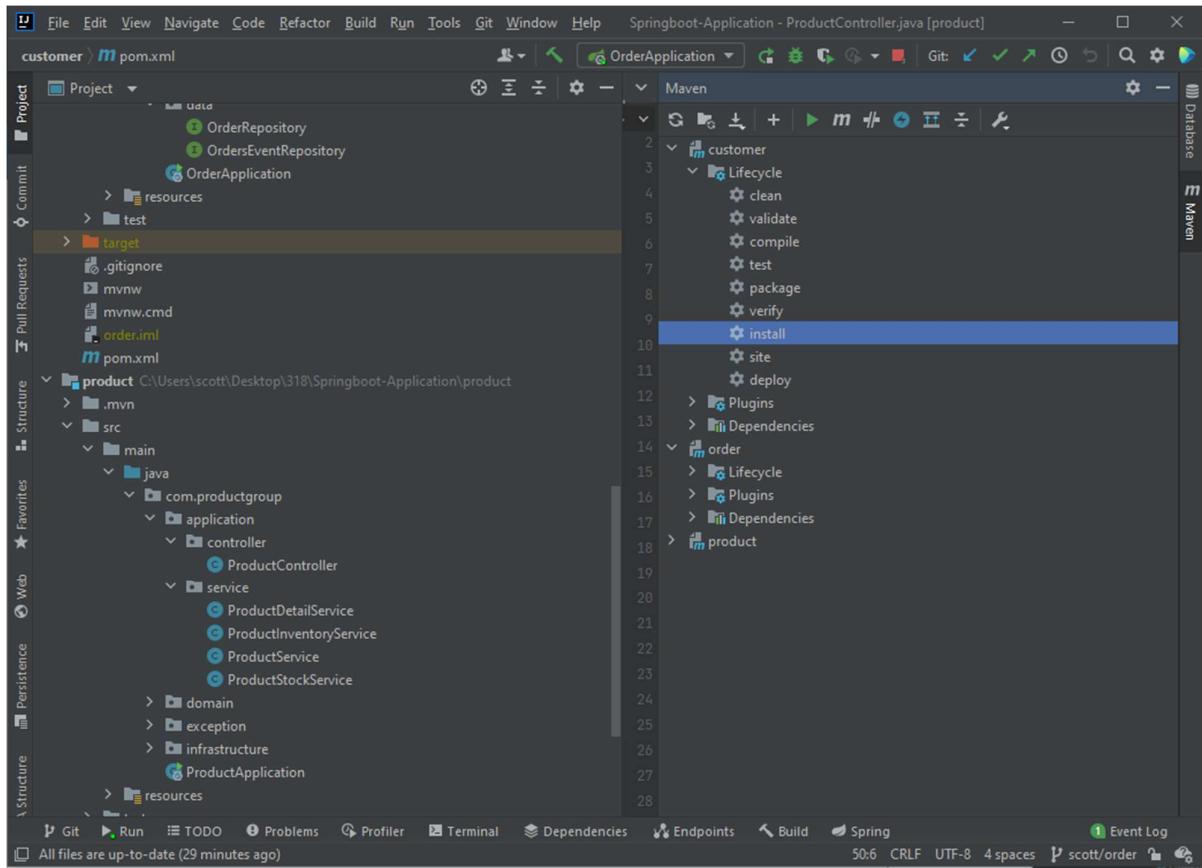

Figure 13.1 - IntelliJ's Maven interface

This functionality constructed the target class along with the FAT jar.

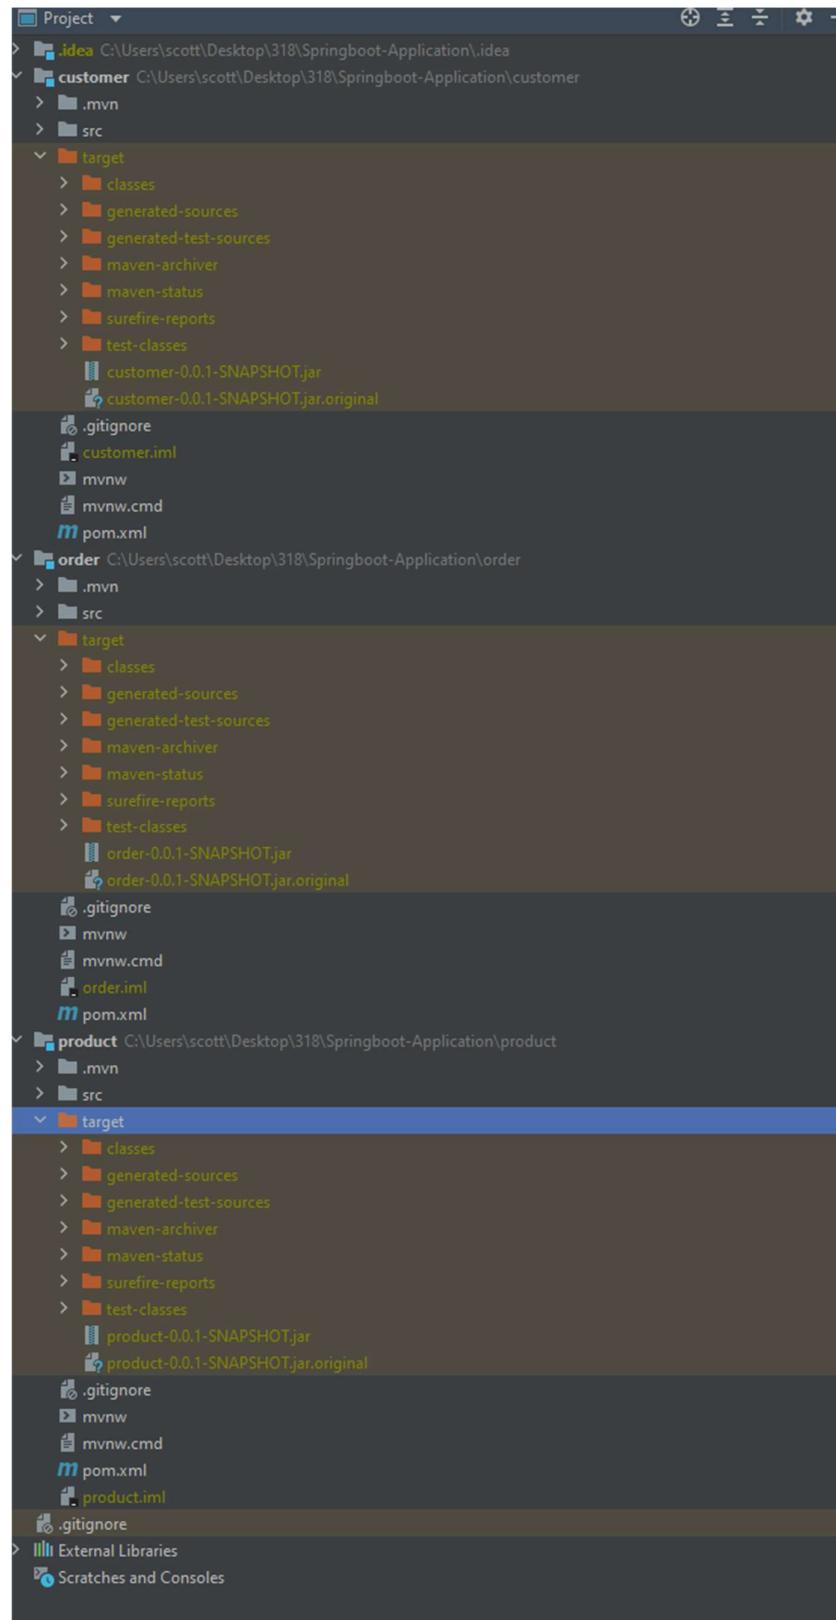

Figure 13.2 - JAR files built in Target Directories

Using Maven's install command will compile the Jar file and install it in the local repository.

Running the Jar Files

To run the 3 Jar Files, one for each project, the command below was inserted via command line whilst in the target directory for each project respectively.

```
java -jar customer-0.0.1-SNAPSHOT.jar
```

```
C:\Users\scott\Desktop\318\Springboot-Application\customer\target>java -jar customer-0.0.1-SNAPSHOT.jar

:: Spring Boot ::          (v2.5.4)

Input Requests

Input request can either be made by making requests through postman.com or by using the curl requests documented in the previous use case documentation. Further details about the usage of endpoints are also documented in the use case tables.

When running the applications, to run input requests: Replace any variables e.g {ORDERID} with the appropriate values

When running POST or PUT requests, there may be endpoints that will accept raw JSON format text. For example,

```
curl --location --request POST 'http://localhost:8081/product' \
```

```
--data-raw '{
    "productCategory": "Beverage",
    "productName": "Sprite",
    "price": 2.35,
    "stockQuantity": 15
}'
```

Endpoints

Application	Endpoints
Customer	<p>GET http://localhost:8080/api/customer</p> <p>http://localhost:8080/api/customer{CUSTOMERID}</p> <p>http://localhost:8080/api/contact/</p> <p>http://localhost:8080/api/contact/{CONTACTID}</p> <p>http://localhost:8080/api/customer/validate={CUSTOMERID}</p>
	<p>PUT Updating a customer http://localhost:8080/api/customer/{CUSTOMERID}?{key}={value}&{key}={value}</p> <p>http://localhost:8080/api/customer/putRaw/{CUSTOMERID} (with inclusion of raw JSON body)</p> <p>Updating a contact http://localhost:8080/api/contact/{CONTACTID}?{key}={value}&{key}={value}&{key}={value}&{key}={value}</p> <p>http://localhost:8080/api/contact/putRaw/{CONTACTID} (With inclusion of raw JSON body)</p> <p>http://localhost:8080/api/customer/{CUSTOMERID}/contact/{CONTACTID}</p>
	<p>POST http://localhost:8080/api/customer (With inclusion of raw JSON body)</p> <p>http://localhost:8080/api/contact (With inclusion of raw JSON body)</p>
Product	<p>GET http://localhost:8081/product</p> <p>http://localhost:8081/product/{PRODUCTID}</p> <p>http://localhost:8081/product/?productName={PRODUCTNAME}</p> <p>http://localhost:8081/productDetail</p> <p>http://localhost:8081/product/checkInventory/productName={PRODUCTNAME}/quantity={QUANTITY}</p>
